#### **Notice**

Medicine is an ever-changing science. As new research and clinical experience broaden our knowledge, changes in treatment and drug therapy are required. The authors and the publisher of this work have checked with sources believed to be reliable in their efforts to provide information that is complete and generally in accord with the standard accepted at the time of publication. However, in view of the possibility of human error or changes in medical sciences, neither the editors nor the publisher nor any other party who has been involved in the preparation or publication of this work warrants that the information contained herein is in every respect accurate or complete, and they disclaim all responsibility for any errors or omissions or for the results obtained from use of the information contained in this work. Readers are encouraged to confirm the information contained herein with other sources. For example and in particular, readers are advised to check the product information sheet included in the package of each drug they plan to administer to be certain that the information contained in this work is accurate and that changes have not been made in the recommended dose or in the contraindications for administration. This recommendation is of particular importance in connection with new or infrequently used drugs.

Neither McGraw-Hill Education nor its licensors shall be liable to you or anyone else for any inaccuracy, error or omission, regardless of cause, in the work or for any damages resulting therefrom. McGraw-Hill Education has no responsibility for the content of any information accessed through the work. Under no circumstances shall McGraw-Hill Education and/or its licensors be liable for any indirect, incidental, special, punitive, consequential or similar damages that result from the use of or inability to use the work, even if any of them has been advised of the possibility of such damages. This limitation of liability shall apply to any claim or cause whatsoever whether such claim or cause arises in contract, tort or otherwise.

## DEDICATION

*To my mentor, Dr. Patricia Butler who, as the Associate Dean of Educational Programs at the University of Texas Medical School at Houston, inspires us all to excellence in the dissemination of knowledge. She has made a tremendous impact on countless medical students and faculty.*

—ECT

*My work on this book is dedicated to the memory of my father, Harry Snyder, and in honor of my mother, Martha Snyder, who inspired me to strive for excellence in helping others. I also dedicate this to my sons, Ciaran and Madden, whom I hope, in turn, to inspire in the same way. And I dedicate this to my wife, Angela, who helps me to be the best person I can.*

—EYS

*To my greatest mentors—my parents Joseph and Farideh. Your guidance and support have allowed me to always follow my passion and dreams. For this, I am eternally grateful.*

—JN

*To my grandfather, Mani Ram Jandial, for creating a family foundation of both loyalty and audacity, principles from which I continue to benefit and hope to pass on to my own beloved sons, Ronak, Kai, and Zain.*

## PREFACE

We appreciate all the kind remarks and suggestions from the many medical students over the past 5 years. Your positive reception has been an incredible encouragement, especially in light of the short life of the *Case Files*<sup>®</sup> series. In this second edition of *Case Files*<sup>®</sup>: *Neuroscience*, the basic format of the book has been retained. Improvements were made in updating many of the chapters including a new case correlation section, in which related cases are referenced to allow the student to review other neurobiological concepts or disease concepts. A new case of subarachnoid hemorrhage has been added. Expanded neuroscience pearls with clinical points highlighting common material covered in the USMLE step 1 have been included. The multiple-choice questions have been carefully reviewed and rewritten to ensure that they comply with the National Board and USMLE format. Through this second edition, we hope that the reader will continue to enjoy learning diagnosis and management through the simulated clinical cases. It certainly is a privilege to be teachers for so many enthusiastic and receptive students, and it is with humility that we present this second edition.

The Authors

## ACKNOWLEDGMENTS

The inspiration for this basic science series occurred at an educational retreat led by Dr. Maximillian Buja, who at the time was the Dean of the medical school. Dr. Buja served as the Dean of the University of Texas Health Science Center at Houston Medical School from 1995 to 2003 before being appointed Executive Vice President for Academic Affairs. It has been such a joy to work together with Drs. Jandial and Snyder and more recently Josh Neman, who are brilliant neuroscientists and teachers.

I would like to thank McGraw-Hill for believing in the concept of teaching by clinical cases. I owe a great debt to Catherine Johnson, who has been a fantastically encouraging and enthusiastic editor. It has been amazing to work together with my daughter Allison, who is a senior nursing student at the Scott and White School of Nursing; she is an astute manuscript reviewer and already in her early career she has a good clinical acumen and a clear writing style. At St. Joseph Medical Center, I would like to recognize our outstanding administrators: Pat Mathews, and Drs. Thomas Taylor and John Bertini. At Methodist Hospital, I appreciate Drs. Mark Boom, Judy Paukert, and Alan Kaplan. and I appreciate Linda Bergstrom's advice and assistance. Without the help from my colleagues, Drs. Konrad Harms, Priti Schachel, and Gizelle Brooks-Carter, this manuscript could not have been written. Most importantly, I am humbled by the love, affection, and encouragement from my lovely wife Terri, and our children: Andy and his wife Anna, Michael, Allison, and Christina.

Eugene C. Toy, MD

## INTRODUCTION

Mastering the extensive and diverse areas of knowledge within a field as broad as neuroscience is a formidable task. It is even more difficult to draw on that knowledge, relate it to a clinical setting, and apply it to the context of the individual patient. To gain these skills, the student learns best with good models, appropriate guidance by experienced teachers, and inspiration toward self-directed, diligent reading. Clearly, there is no replacement for education at the bench. Even with accurate knowledge of the basic science, the application of that knowledge is not always easy. Thus, this collection of patient cases is designed to simulate the clinical approach and stress the clinical relevance to the neurosciences. However, it should also be remembered that, although we often talk about basic research as going “from bench to bedside”, it is actually the inquisitiveness and insight and hypotheses of the clinician that drives basic researchers to ponder certain questions at the bench. Hence the pathway of “bedside-to-bench” is equally as powerful. It is that pathway that we hope this book might also stimulate among its readers.

Most importantly, the explanations for the cases emphasize the mechanisms and structure–function principles rather than merely rote questions and answers. This book is organized for versatility to allow the student “in a rush” to go quickly through the scenarios and check the corresponding answers or to consider the thought-provoking explanations. The answers are arranged from simple to complex: the bare answers, a clinical correlation of the case, an approach to the pertinent topic including objectives and definitions, a comprehension test at the end, neuroscience pearls for emphasis, and a list of references for further reading. A listing of cases is included in Section III to aid the student who desires to test his/her knowledge of a certain area or to review a topic including basic definitions. We intentionally used open-ended questions in the case scenarios to encourage the student to think through relations and mechanisms.

# Approach to Learning Neurosciences

**Part 1.** The Big Picture

**Part 2.** Know the Tracts

**Part 3.** Understand the Terminology

## The Big Picture

---

Neuroscience is unique in that it incorporates an understanding of science on multiple levels, from a molecular understanding of events such as with receptors, at the synaptic level, to a global understanding of the sensory/motor tracts and their spatial interactions. It is by understanding all these concepts that a student can better grasp the clinical presentations of neurological disorders and the theory behind treatment options. The student should thus approach each neuroscience topic from both aspects if applicable. For example, when studying **multiple sclerosis (MS)**, the student should understand that on the molecular level this disease involves destruction of **oligodendrocytes**, which are responsible for creating and maintaining **myelin sheaths** around axons of the central nervous system. The student should then review the **nodes of Ranvier** and concepts pertaining to **saltatory conduction**. Next, the student should take a step back and look at the condition from a neuroanatomic perspective. For example, if the patient with MS presents with left impaired adduction on right gaze, but has normal convergence, and normal left abduction on left gaze, not only should the student be able to diagnose the patient with a left **intranuclear ophthalmoplegia (INO)**, but should also understand that the lesion is in the left **medial longitudinal fasciculus (MLF)** and then proceed to review the anatomy of the MLF tract (ie, that the left MLF yokes the left cranial nucleus VI to the right cranial nucleus III). The student should strive for an understanding such that symptoms should make sense rather than rely on blind memorization!

## Know the Tracts

---

There is no way to avoid it; the student has to memorize the various neural tracts (ie, spinothalamic tract, corticospinal tract, etc.) **forward and backward**. It is easier to first take each tract separately and memorize the exact pathway the neurons in that tract travel throughout the body, noting any decussations or synapses so that the student can determine whether lesions would have ipsilateral (same side as the lesion) or contralateral (opposite side of the lesion) symptoms, or which nuclei are involved. The **second step** would be to **synthesize this information** by taking various cross-sections of the nervous system (from the spinal cord to the brain) and being able to identify where each tract is, reviewing at the same time where that tract is coming from upstream and going to downstream. It is important to note that the terms *upstream* and *downstream* may be different spatially, depending on the tract referred to. For example, *upstream* means a cross-section *above* the one being studied when referring to the corticospinal tract since the tract travels caudally. However, *upstream* means a cross-section *below* the one being studied when referring to the spinothalamic tract since this tract travels cranially (from the peripheral inputs to the cortex). The third step involves knowing the cross-sections so thoroughly that the student can draw any cross-section, incorporating all the tracts and nuclei involved in that cross-section. Throughout the studying process, the students should be asking themselves, *if there is a lesion in this structure or at this level, what symptoms will be manifested?*

## Understand the Terminology

---

Although it takes less effort to memorize medical terminology without understanding the origin of the term, it is much more effective in the long term to understand the reason behind the name of a structure or pathological condition. Going back to our example of MS, the *scleroses* refers to the plaques or lesions in the white matter, while the term *multiple* refers to variety in location and time. In other words, in order to diagnose MS, a patient must have at least two anatomically separate lesions occurring at two distinct time periods. Similarly, the student should not just simply memorize structures like the previously mentioned *spinothalamic tract* and *corticospinal tracts*. Rather, the student should understand that the *spinothalamic* tract receives input at the *spinal cord* level that travels to and synapses in *thalamic* nuclei. Likewise, the *corticospinal* tract sends information originating from cells in motor *cortex* to the *spinal cord*, which eventually coordinates muscular movement via the lower motor neurons.

### NEUROSCIENCE PEARLS

- ▶ The student should seek to understand the neuroscience on a molecular level, synaptic level, and a higher level such as sensory/motor tract level.
- ▶ An understanding of the neural tracts should allow synthesis and drawing the

cross-sections from brain to spinal cord.

- ▶ The student should strive to understand medical terminology rather than blindly memorizing.

**Clinical Cases**

## CASE 1

A 53-year-old man presents to the emergency department following a new-onset generalized seizure. After recovery from the seizure period, he is alert and oriented to person, place, and time, although he has no specific memory of the seizure. There are no neurological deficits noted on the physical examination, but magnetic resonance imaging (MRI) and positron emission tomography (PET) scans indicate the presence of a sizable lesion. The patient undergoes surgery for resection of the malignancy and is diagnosed with a malignant primary brain tumor, which is identified as a glioblastoma multiforme (GBM). The neurosurgeon's plan is to place the patient on long-term seizure prophylaxis and steroids in combination with stereotactic radiotherapy.

- ▶ What other types of tumors are most closely related to this patient's malignancy?
- ▶ What are the imaging findings most characteristic of these types of tumors?
- ▶ What are the hallmark pathological findings of these types of tumors?

### ANSWERS TO CASE 1:

#### Cell Types of the Nervous System

*Summary:* A 53-year-old man with new-onset seizure and a left parietal lobe mass undergoes surgery to resect a primary brain tumor, diagnosed as a GBM. He also receives adjuvant radiation treatment.

- **Related tumors:** Low-grade astrocytomas and anaplastic astrocytomas.
- **Imaging characteristics:** A ring-enhancing lesion in the left parietal lobe with surrounding edema and mass effect.
- **Neuropathological findings:** GBMs exhibit marked hypercellularity, nuclear pleomorphism, microvascular proliferation, and pseudopalisading of tumor cells around areas of necrosis.

#### CLINICAL CORRELATION
